1 General Information

1.1 Warnings

\land Warning

This preview delivery is not for productive usage and not affected by service-level agreements.

🔔 Warning

Custom configuration or template files are potentially not updated automatically. After the update, please always check for files with a **.dpkg-new** or **.rpmnew** suffix and merge the changes manually. Configuration file changes are listed in their own respective section below but don't include changes to template files. For details about all the configuration files and templates shipped as part of this delivery, please read the relevant section of each package.

1.2 Delivery Comment

This delivery was requested with following comment:

```
DMF Worker 1.1.0 Preview Delivery 1
```

1.3 Install Package Repository

This delivery is part of a restricted preview software repository:

```
https://software.open-xchange.com/components/dmf-worker/preview/1.1.0/RHEL7
https://software.open-xchange.com/components/dmf-worker/preview/1.1.0/DebianStretch
https://software.open-xchange.com/components/dmf-worker/preview/1.1.0/DebianBuster
```

1.4 Build Dependencies

This delivery was build with following dependencies:

RedHat:RHEL-7,Debian:Stretch,Debian:Buster

2 Worker Install

The DMF Worker is a stateful service which processes the migration jobs that are added to the Migration Database queue by the DMF Scheduler. How it processes those jobs is configurable. This guide will discuss the instation of the Worker as well as all configuration options.

2.1 Install the Package

The Worker can be installed with package <code>open-xchange-dmf-worker</code>. You will find that the package requires JRE8.

Example:

apt-get install open-xchange-dmf-worker

This package registers a systemd service script called dmf-worker.

You will find all related application files under /opt/open-xchange/dmf/worker.

Where you install the Worker(s) is completely based upon how you plan to use it. While DMF stands for *Dovecot* Migration Framework, in reality, it is more like a *Mail* Migration Framework because

nothing restricts you from using it for just Dovecot migrations. In fact, bare bones, it is just a job processing framework that allows you to plug in any Job Worker to process your job. However, this guide will assume that you are using DMF for a Dovecot target migration. If you want to know more about using it outside of Dovecot, see the DMF Beyond Dovecot documentation.

For this purpose, you will install one DMF Worker on every Dovecot backend that you plan to migrate users into. DMF must have execute permission on the Dovecot doveadm shell utility.

2.2 Configure the Application

Once installed, you can find the configuration file at: /opt/open-xchange/dmf/worker/etc/dmf-worker.yml All properties can also be set as environment variables.

For instance, http.admin.username would be HTTP_ADMIN_USERNAME, while it would be configured as follows in dmf-worker.yml:

```
1 http:
2 admin:
3 username: admin
```

Environment variables have precedence over configuration file settings.

2.2.1 Configure HTTPS

The Worker does not expose a custom API, however, it exposes all built in Micronaut Endpoints as well as a metrics endpoint for prometheus at https://worker:8443/prometheus.

Review the Micronaut HTTPS documentation and examples to configure TLS.

Use keys under micronaut.ssl to configure the server. The default configuration expects a private key and the corresponding certificate in /opt/open-xchange/dmf/certs/keystore.p12

This file can be easily generated by running the following:

/opt/open-xchange/sbin/dmf-worker-gen-certs -d /opt/open-xchange/dmf/certs

The script dmf-worker-gen-certs is installed as part of the open-xchange-dmf-worker package. In addition to keystore.p12 for the Worker, the script also generates worker.p12 in the same directory. This file contains the self-signed certificate, and can be used by clients to verify the identity of the Worker.

As a side-effect, the script also generates worker.pem, which is the same self-signed certificate in a more popular format. It can be used by browsers and other clients, but is not necessary for DMF operation.

If the Worker operates behind a web server or any other proxy which performs the actual TLS termination, and also uses a self-signed certificate, then its certificate can be converted to the right format manually, using Java's keytool. See the last step in the dmf-worker-gen-certs script for an example.

An example configuration:

```
1 micronaut:
2 ssl:
3 enabled: true
4 key-store:
5 path: file:/opt/open-xchange/dmf/certs/keystore.p12
6 type: PKCS12
7 password: verysecretpassword
8 port: 8443
```

2.2.2 Configure Authentication

Basic authentication is used to authenticate HTTP clients. This can be configured like so:

```
1 http:
2 admin:
3 username: admin
4 password: verysecretpassword
```

2.2.2.1 Endpoints All built-in Micronaut Endpoints, or custom endpoints, are restricted by default, but any can be configured to be accessed anonymously:

```
1 endpoints:
2 info:
3 sensitive: false
```

2.2.2.2 Security Restricting access to HTTP resources is enabled using the property:

• micronaut.security.enabled

You can also restrict clients by IP by using the micronaut.security.ip-patterns property.

```
1 micronaut:
2 security:
3 enabled: true
4 ip-patterns:
5 - 127.0.0.1
6 - 192.168.1.*
```

2.2.3 Configure Data Source

The Worker must talk to the Migration Database and this is the only data source you need to configure. Aside from basic connection properties, the data source is highly configurable using any of the JDBC Hikari properties.

🚺 Info

The configured database user must have read and update permissions on the migration database tables.

Example configuration:

```
1 datasources:
2 default:
3 url: jdbc:mysql://dmf-db:3306/migration
4 username: worker
5 password: verysecretpassword
6 dialect: MYSQL
7 driverClassName: org.mariadb.jdbc.Driver
```

2.2.4 Configure Executor Pools

The DMF Worker makes use of Java executor pools to run migration jobs in parallel. You can find all configuration properties for these pools at Micronaut Thread Pools.

In the Worker configuration, there are two pools that you should consider configuring. The important thing is the number-of-threads. The default is 100. If you plan to allow the Worker to run more than 100 jobs in parallel, then you should adjust this number. For instance, if you plan to allow your Workers to process 400 jobs in parallel, then you should set this value to at least 400 for both the worker-executor and command-executor executor pools.

```
1 micronaut:
2 executors:
3 worker-executor:
4 name: worker-executor
5 type: fixed
6 number-of-threads: 400
7 command-executor:
8 name: command-executor
9 type: fixed
0 number-of-threads: 400
```

🕕 Info

The executor pool max threads is not the property that the Worker uses to determine the max number of jobs it will try to process in parallel. It is only a way to configure compute resources for the DMF application. This means that you should set these values to the max number of jobs that you will ever configure the Worker to process in parallel. It is not possible to change this number while the application is running. However, you can inform the Worker to attempt to process more or less jobs during runtime by using the Scheduler backends REST API and modifing the Worker's max threads.

2.2.5 Configure Identity

Each Worker has an identity so that you can identitfy them when managing their settings, but also so that you can trace where a migration job was processed. There are two parts to a Worker identity: target and memberid.

The Worker target should represent the Target platform. For instance, if you have a platform called "cloud", you might name the Target "cloud" and then set this as the target property of every Worker that will migrate users to this platform. It is important to use the same Target name for all Workers in the same platform to prevent multiple Workers from migrating to the same target mailbox at the same time. Therefore, ensuring a 1-1 relationship between user and target mailbox.

\land Warning

If your customer/client is still using the deprecated legacy API, then you must use a single Target called "default". This will require you to deploy a separate DMF platform for other Targets, so they should update to the new API ASAP.

The Worker's memberid must be unique within the Target. No Worker should ever have the same memberid as another Worker who has the same target identity.

\land Warning

1

23

4

5

There is not a mechanism in place to stop a Worker from stealing the identity of another Worker so care should be taken.

```
dmf:
worker:
identity:
target: cloud
memberid: 1
```

Once the Worker has been started and registered with the Migration Database, you can manage it with the Scheduler Admin Backends REST API with the Target cloud and name cloud/1:

```
1 curl -X 'GET' \
2 'https://localhost:7443/dmf/admin/api/v2/targets/cloud/backends/cloud%2F1' \
3 -H 'accept: application/json' \
4 -H 'Authorization: Basic YWRtaW46cGFzc3dvcmQ='
```

2.2.6 Configure Sources

The Worker has the ability to service any number of DMF Sources. Remember that a DMF Source is created using the Admin HTTP API and represents a Source platform. For this purpose, we will have two Sources: ["POD_1", "POD_2"]. Workers will get jobs for all Sources based on priority, then time of submission.

Configure the Worker to service both Sources:

```
dmf:
1
2
3
4
      worker:
        sources:
           - "POD_1"
5
           - "POD_2"
```

2.2.7 Configure State

By default, the Worker is configured to start polling for migration jobs when it is started. If you want to disable so that you can start the Worker, but not start polling for jobs until a later time, then you can change the initial state to STOPPED.

```
dmf:
  worker:
    state:
      initial: STOPPED
```

🗊 Info

1

2 3

Once the Worker has been started and registered with the Migration Database, this can be changed by using the Scheduler Admin REST API. At this point, the database value will override the application configuration.

```
curl -X 'PATCH' \
1
     'https://worker:8443/dmf/admin/api/v2/targets/cloud/backends' \
23456
     -H 'accept: application/json' \
     -H 'Authorization: Basic YWRtaW46cGFzc3dvcmQ=' \
     -H 'Content-Type: application/json' \
     -d '{
7
     "name": "cloud/1",
8
     "initialState": 1
9
   י {
```

Now that we set it to 1 (STARTED), if the Worker is ever restarted, it will start polling for jobs.

2.2.8 Configure Job Settings

2.2.8.1 Job Cache The Worker collects prospective migration jobs in a local cache in order to reduce the number of sorting queries performed since the database does not actually provide a priority queue. If you find that the Worker has seemingly unnecessary high memory usage, then it may be beneficial to reduce the size of the cache, or in the case of high database load reduce the refresh rate.

```
dmf:
2
     worker:
3
       jobs:
          cache:
5
            size: 400
            referesh: 1m
```

1

4

6

2.2.8.2 Max Jobs This is the max number of migration jobs that the Worker will process in parallel. Keep in mind that this value should be less than or equal to the number-of-thread configured

for the worker-executor executor pool. If it is not, then jobs will be queued within the executor and not executed until a thread is freed, thus potentially blocking another Worker from processing

```
1 dmf:
2 worker:
3 jobs:
4 max: 400
```

The max number of jobs you want to execute depends on the sizing of the server that the Worker is running, the Worker features you have enabled, and the migration command you are using. If unknown, it is recommened to start low and scale up. It is easy to increase the max jobs, however, difficult to stop jobs or handle an overloaded server.

🕕 Info

it

Once the Worker has been started and registered with the Migration Database, this can be changed by using the Scheduler Admin REST API. At this point, the database value will override the application configuration.

```
1 curl -X 'PATCH' \
2 'https://worker:8443/dmf/admin/api/v2/targets/cloud/backends' \
3 -H 'accept: application/json' \
4 -H 'Authorization: Basic YWRtaW46cGFzc3dvcmQ=' \
5 -H 'Content-Type: application/json' \
6 -d '{
7 "name": "cloud/1",
8 "maxThreads": 120
9 }'
```

2.2.9 Configure Command Logging

There are three ways to configure command execution output. This is the output whenever a native command is executed, for instance, like the migration command.

- 1. file: Redirects all output to a file. You can specify the location and file naming as well as if the file should be removed upon successful execution of the command.
- 2. logger: Redirects all output to the Worker application logger
- 3. off: silences all output

```
1
    dmf:
23456789
      worker:
        command:
          logging:
            type: file
            file:
              # The log file name format. You can use the following specifiers:
                  * source: the source name
              #
                  * user: the target uid
              #
10
              #
                  * phase: the migration phase (pre-sync, cutover)
11
              #
                  * job: the job id
12
                 * date: the YYYY-MM-DD date
              #
13
              format: "%(source)-%(user)-user-migration.log"
14
              location: /var/log/dmf
15
              delete-on-success: false
```

2.2.10 Configure Doveadm

This section only discusses how to setup the doveadm configuration, but you should review the DMF Doveadm Features documentation for more information on what each property is responsible for and how you should use it.

Within DMF, we have a concept of a Worker type. For this purpose, we will use the type doveadm which uses the doveadm command line tool supplied by Dovecot to process migration jobs. The

documentation DMF Beyond Dovecot provides information about the other Worker types.

As already seen when configuring the Sources, the Worker supports migrating from multiple Sources to a Target. So, the doveadm Worker allows you to configure it per Source.

The configuration looks like:

You can apply a special key called default and then all doveadm specific properties under that. In which case, the Worker will use this configuration if there is not an override.

To override the default, use the source name as the key:

```
1 dmf:
2 doveadm:
3 path: "/usr/bin/doveadm"
4 source:
5 default:
6 ...
7 POD_1:
8 ...
```

Now, when the Worker gets a migration job for POD_1, it will use the POD_1 doveadm configuration, but if it gets a job for POD_2, then it will use the default doveadm configuration.

2.3 Manage the Application

The application can be started/stopped/restarted using the systemd script dmf-worker.

Start example:

```
systemctl start dmf-worker
```

Stop example:

```
systemctl stop dmf-worker
```

A Warning

The DMF Worker is very stateful in a number of ways. It is extremly important to only stop the application while it is processing migraiton jobs in critical situations.

The proper way to stop a DMF worker is:

2.3.1 1. Pause the Worker

By using the DMF Scheduler Admin REST API.

```
1 curl -X 'PATCH' \
2 'https://scheduler:8443/dmf/admin/api/v2/targets/default/backends' \
3 -H 'accept: application/json' \
4 -H 'Authorization: Basic YWRtaW46cGFzc3dvcmQ=' \
5 -H 'Content-Type: application/json' \
6 -d '{
7 "name": "default/worker1",
8 "command": "PAUSE"
9 }'
```

2.3.2 2. Check and Confirm on no Running Jobs

Once you have confirmed that the Worker has no running jobs, you can stop it. This can be confirmed by using the Scheduler API to get the current status of the Worker. If the Worker is paused and has 0 threads, then it is not running any migration jobs.

```
1 curl -X 'GET' \
2 'https://localhost:7443/dmf/admin/api/v2/targets/default/backends/default%2Fwoker1' \
3 -H 'accept: application/json' \
4 -H 'Authorization: Basic YWRtaW46cGFzc3dvcmQ='
```

```
1 {
2 "name": "default/worker1",
3 "target": "default",
4 "initialState": 1,
5 "maxThreads": 200,
6 "status": 0, <-- 0 is paused
7 "threads": 0, <-- 0 threads means 0 jobs running
8 "command": null,
9 "updated": "2021-04-12T21:34:56.00Z"
10 }</pre>
```

2.3.3 3. Stop the worker either using the Admin API or service.

```
1 curl -X 'PATCH' \
2 'https://scheduler:8443/dmf/admin/api/v2/targets/default/backends' \
3 -H 'accept: application/json' \
4 -H 'Authorization: Basic YWRtaW46cGFzc3dvcmQ=' \
5 -H 'Content-Type: application/json' \
6 -d '{
7 "name": "default/worker1",
8 "command": "STOP"
9 }'
```

The Worker will stop polling for jobs and the application will close.

3 Doveadm Features

By default, the DMF Worker will use the Doveadm Worker type to process migration jobs. This section lists all features, what they do, and how to configure them.

The below configuration examples assume that the key is under dmf.doveadm.source.<sourceName>. For instance, if the required configuration is to set my-property to true, then the following are equivalent:

```
1 ...:
2 my-property: true
3 ----
4 dmf:
5 doveadm:
6 source:
7 mySource:
8 my-property: true
```

🚺 Info

A migration job will be successful unless something is misconfigured, a fatal unknown exception occurs, or the migration command fails after the max retries.

3.1 Analyze Log

The Worker will create a doveadm log analyzer which can be used for finding errors (some which could be automatically resolved) and mailbox statistics.

By setting to false, the following functionality will be lost:

- Find and resolve duplicate UIDs
- Find and resolve failed save due to timeout
- Collect errors for the job response
- Collect sync mail statistics

Configuration:

1 2

```
analyze-log: true
```

3.2 Move Duplicates

This feature requires analyze-log.

While rare, it is possible that the source mailbox contains multiple messages with the same UID causing a duplicate UID situation. This is detected by finding log messages containing "Expunged message reappeared in session". Any UIDs with this issue will be extracted and an attempt to fix them will be made. This error causes the migration command to fail. If there is a retry configured, the duplicate fix will be performed prior to the command retry.

Step:

1

- 1. The Worker will connect to the source host through an imap connection
- 2. Create a new mailbox named lost+found-<originalFolder> under the folder that the UID is within.
- 3. Copy the message from the original folder to the lost and found folder
- 4. Expunge the original mail

Configuration:

```
. . . :
2
     move-duplicates: true
```

If a duplicate message is found at any point during the migration (even if it is resolved), it will be included in the Migration details field in the dsync operation metadata as invalid.

Example:

```
123456789
     {
        "dsync": {
           ..,
          "invalid": {
             "INBOX": [
            "uid1",
            "uid2"
            ]
          }
10
       }
11
    }
```

IMAPC Inbox 3.3

Currently, this feature executes shell commands cp and chown on a users home mail path as well as delete folders that it creates through the Java API. Unfortunately, this requires DMF to be executed with a user with this permission level.

A hack to speed up delta syncs with pop3 uidl. It copies the local user's INBOX mailbox to:

• <userHome>/imapc/.INBOX/.INBOX

This is done after the pre migration command but before the migration command.

Steps:

- 1. Get the user's home path with: doveadm user -f home <userUid>
- 2. Get the user's INBOX path with: doveadm mailbox path -u <userUid> INBOX
- 3. Copy the INBOX to homePath/.INBOX.INBOX: /usr/bin/cp -a homePath/.INBOX.INBOX
- 4. Change the home path owner to vmail: /bin/chown -R vmail:vmail homePath

If configured to remove the created INBOX path, this is done after the migration command, regardless of outcome, but before the post/failure migration command.

Configuration:

```
1 ...:
2 copy-imapc-inbox: true
3 remove-imapc-path: true
```

3.4 Metacache

Executes metacache flush and/or metacache clean for the target user. This is only done after a successful migration command but before the post migration command.

Configuration:

```
1 ...:
2 flush-metacache: true
3 clean-metacache: true
```

3.5 Move User

This requires that the director property is enabled and the http configuration is complete.

This will make a move user request to the configured doveadm HTTP API for the target user.

Steps:

- 1. Get Workers IP address
- 2. Get the list of Dovecot backends from the HTTP API directorStatus command
- 3. Verify that the Worker's IP is one of the backends
- 4. Move the target user to this backend with the HTTP API directorMove command

Configuration:

```
1
    micronaut:
 2
3
      http:
        services:
 4
5
          # Configure the HTTP client connection properties for the doveadm HTTP API
          # https://docs.micronaut.io/latest/guide/configurationreference.html#io.micronaut.
               http.client.ServiceHttpClientConfiguration
6
7
9
10
11
          doveadm:
             ssl:
               enabled: true
               trust-store:
                 path: file:/opt/open-xchange/dmf/certs/doveadm.p12
                 password: verysecretpassword
12
                 type: PKCS12
13
    . . . :
14
      director:
15
        enabled: true
16
        move-user: true
```

```
17 http:
18 url: "https://doveadmhttpapi"
19 username: admin
20 password: verysecretpassword
21 director-tag: aa
22 use-only-tagged: false
```

3.6 Fetch Container

Gets the userdb_container value in the configured container file for the value of imapcoptions defined for the user. If imapcoptions is not set for the user, but this is enabled, then it wont be used. The found value can be injected into migration commands with %{mdb:container}.

Configuration:

```
1 ...:
2 fetch-container: true
3 container-file: /etc/dovecot/passwd.container
```

3.7 Parallel Writes Retry

If retries are configured and a failure has occurred with error message containing failed: PUT .+ failed: Absolute request timeout expired, then the following setting override will be added to the migration command prior to the retry:

-o plugin/obox_max_parallel_writes=1

3.8 Mail Count

Properties to configure counting of mailbox messages and size.

3.8.1 Pre Mail Sync

Collect local mailbox stats after the pre migration command but before the migration command.

```
The result is logged as: destination system statistics before sync. messages: {}, size: {} (bytes)
```

Configuration:

```
1 ...:
2 count:
3 pre: true
```

3.8.2 Mail Sync

This feature requires analyze-log.

Count the number of saved and expunged mails during the migration command. The results are stored with the job response as the sync saved and expunged message counts.

Configuration:

1

2 3

```
...:
count:
sync: true
```

3.8.3 Post Mail Sync

Collect local mailbox stats after the successful migration command but before the post migration command. The results are stored with the job response as the target mailbox size and message count.

Configuration:

```
1 ...:
2 count:
3 post: true
```

3.8.4 Post Mail Sync Remote

Collect the remote mailbox stats after the successful migration command but before the post migration command. The results are stored with the job response as the origin mailbox size and message count.

Configuration:

1

23

1

```
...:
count:
remote: true
```

There are four ways to configure how the remote count will be executed:

3.8.4.1 IMAPC Protocol This feature requires the imapc configuration or all imap connection properties included with the migration job.

If the user's Sourcehost definition does **not** use a status command, and the remote-protocol is set as imapc, then a default remote count command will be used.

This command is:

```
doveadm -f tab -o imapc_ssl=<imaps/no> -o imapc_host=<sourcehost> -o imapc_user=<sourceUid
> -o imapc_password=<password> -o imapc_port=<port> -o mail=imapc: mailbox status -u <
    sourceUid> "messages vsize" INBOX/* INBOX *
```

Configuration:

```
1 ...:
2 count:
3 remote-protocol: imapc
4 imapc:
5 host: host.with.imap
6 port: 143
7 prefix:
8 master-user: admin
9 master-password: verysecretpassword
```

3.8.4.2 Doveadm Protocol This feature requires the doveadm configuration.

If the user's Sourcehost definition does **not** use a status command, and the remote-protocol is set as doveadm, then a default remote count command will be used.

This command is: doveadm -f tab -o doveadm_password=<doveadm.password> mailbox status u <sourceUid> -S <doveadm.host>:<doveadm.port> "messages vsize" INBOX/* INBOX *

Configuration:

...:

```
2 count:
3 remote-protocol: doveadm
4 doveadm:
5 host: host.with.doveadm
6 port: 24245
7 password: verysecretpassword
```

3.8.4.3 Status Command If the user's Sourcehost definition **does** include a status command, then that command will be used. The command must use the mailbox status doveadm subcommands as well as a tab formatter.

3.8.4.4 Configuration To override all other options, you can specify the remote count command using configuration.

Configuration:

```
1
    . . . :
2
3
4
5
6
7
8
9
10
      count:
        remote-command:
          name: doveadm
           options:
             - name: -f
               value: tab
             - name: -o
               value: "imapc_user=%{mdb:ruid}"
             - name: -o
11
12
13
14
15
16
17
               value: "imapc_password=%{conf:imapc_master_password}"
             - name: -o
               value: "imapc_host=%{mdb:sourcehost}"
             - name: -o
                value: "mail=imapc:"
           sub-command:
             name: mailbox status
18
19
20
21
22
23
             arguments:
               - "messages vsize"
               - "INBOX/*"
               - "INBOX"
                - "*"
             options:
24
                - name: -u
25
                  value: "%{mdb:uid}"
```

3.9 Migration Retry

Properties to configure retrying the migration command after a failure.

3.9.1 Max Retries

Max number of retries for doveadm sync errors which are non fatal. To override any specific error code, use code-max.

Override for max on the error code level.

Configuration:

```
1 ...:
2 retry:
3 max: 1
4 code-max:
5 75: 5
```

3.9.2 Retry Sleep

The amount of time in ms to sleep before retrying the migration command. To override any specific error code use code-sleep.

Override for sleep on the error code level.

Configuration:

5

```
1
   . . . :
2
3
     retry:
       sleep: 5000
4
        code-sleep:
          75: 15000
```

3.10 Commands

The Doveadm DMF Worker has the ability to execute various commands throughout the migration job. This includes the main migration command. The migration command must be a Doveadm-Sync command. If you are looking to do something else, then you likely do not want to use the Doveadm DMF Worker, and should look into the DMF Beyond Dovecot documentation. Any other command constraints will be listed in the following sections.

3.10.1 Property Injection

Commands can have properties injected into them. By default, you can do the following:

- MDB formatters are used like %{mdb:X}, where X can be: md5path, 2chrruid, container, uid, ruid, sourcehost, source, sourcepasswd, imapcoptions, email, sourceport, imapc_ssl, exclude
- Conf formatters are used like %{conf:Y}, where Y can be: imapc host, imapc master password, imapc_master_user, imapc_prefix, imapc_port

You can also define custom properties that can be injected into commands. You will use the same %{conf:Y} formatter where Y will be defined under the property:

dmf.doveadm.source.<sourceName>.command.inject

For example, if you define:

```
1
    . . . :
      command:
23
        inject:
           test: value
```

then you can have a command doveadm -o setting=%{conf:test} and the command would resolve tO doveadm -o setting=value

The order of injection is:

- 1. custom inject properties
- 2. imapc properties from config
- 3. user properties from job

All commands support property injection.

3.10.2 Pre Mail Sync

This can be any shell command and it is executed prior to the migration command. An applicable example would be to specify a shell script that takes the sourceUid and locks the source mail account.

Configuration:

1 2 3 4 5 6 7 8 9 10 11 . . . : command: sync: pre: name: echo arguments: - pre - sync - "%{mdb:uid}" cutover: pre: 12 name: echo 13 arguments: 14 15 - pre - cutover 16 - "%{mdb:uid}"

3.10.3 Mail Sync

Overrides the migration command. This must be a Doveadm-Sync command.

```
Configuration:

1 ...:

2 command:

3 sync:

4 sync:

5 name: doveadm

6 ...

7 cutover:

8 sync:

9 name: doveadm

10 ...
```

3.10.4 Post Mail Sync

This can be any shell command and it is executed after a successful migration command. An applicable example would be to specify a shell script that takes the sourceUid or targetUid and changes a proxy status.

Configuration:

```
1
2
3
4
5
6
7
8
9
10
11
     . . . :
       command:
         sync:
           post:
              name: echo
              arguments:
                 - post
                - sync
                - "%{mdb:uid}"
         cutover:
           post:
12
13
              name: echo
              arguments:
14
                - post
15
                 - cutover
16
                 - "%{mdb:uid}"
```

3.10.5 Mail Sync Failure

This can be any shell command and it is executed after a migration command failure. If retries are configured, this is only executed if the last retry is still a failure. An applicable example would be to specify a shell script that takes the sourceUid and unlocks the source mail account.

Configuration:

1	:
1 2 3 4 5 7 8 9 10	command:
3	sync:
4	failure:
5	name: echo
6	arguments:
7	- failure
8	- sync
9	- "%{mdb:uid}"
	cutover:
11	failure:
12	name: echo
13	arguments:
14	- failure
15	- cutover
16	- "%{mdb:uid}"

3.11 Configurable Failures

By default, the only things that will mark a migration as FAILURE, is a misconfiguration or a failed migration command. However, the other steps in the migration can be configured to mark the migration as FAILURE if they fail.

Note: This will also cause the post migration failure command to be executed. Currently it is only executed if the migration command fails.

This feature is useful when, for instance, you configure a post migration command to do some processing of the mail data, and if that processing fails, then the user should not be marked as migrated.

By default, the doveadm migration command is the only step that will mark a migration as failed if it fails. All other steps by default will not mark a migration as failed if they fail, however, they can be configured to do so.

Configuration:

```
1 ...:
2 failure-flags:
3 cutover:
4 post-migration-command: true
```

Supported configuration keys: INCLUDE-SNIPPET-25: markdownInclude/2/snippet-25.txt

3.12 Order of Operations

The migration job order of operations (only if configured):

- 1. Move User
- 2. Pre Mail Sync Command
- 3. Copy IMAPC Inbox
- 4. Pre Mail Sync Count
- 5. Mail Sync(Migration) Command + Mail Sync Count
- 6. Remove IMAPC Inbox

Successful Migration Command:

- 1. Post Mail Sync Count
- 2. Post Mail Sync Remote Count
- 3. Flush Metacache
- 4. Clean Metacache
- 5. Post Mail Sync Command

Failed Migration Command:

1. Mail Sync Failure Command

3.13 Job Response Details

Each operation will provide a status in the Migration Job Response details field. This field is a JSON array with the results from the order of operations.

The operation will only be included if the feature supporting that operation is enabled. For instance, if there is not a Pre Mail Sync Command configured, then there will not be a "pre migration command" operation in the details.

Example:

```
1 2 3 4 5 6 7 8 9 10 11 12 13 4 15 16 7 11 12 13 14 15 16 7 17
     Ε
       {
          "pre migration command": {
            "success": true,
            "command": "echo pre mail sync user1",
            "exitCode": 0,
            "errors": []
         }
       },
       {
         "copy imapc inbox": {
            "success": true,
            "errors": []
         }
       },
       {
         "count local mailbox pre sync": {
18
            "success": true,
19
            "command": "doveadm -f tab mailbox status -u user1 \"messages vsize\" INBOX/* INBOX
                 *",
20
            "exitCode": 0,
21
22
23
24
25
            "errors": []
         }
       },
       {
          "dsync": {
26
27
            "success": true,
            "command": "doveadm -o imapc_host=host -o imapc_user=user1 -o imapc_password=<hidden</pre>
                > -o imapc_port=143 backup -R -u user1 imapc:",
28
            "exitCode": 0,
29
30
31
32
33
34
35
36
            "errors": [],
            "attempts": 1,
            "saved": {
"INBOX": 50,
              "special": 25
            },
            "expunged": {
              "special": 5
37
            },
38
39
40
            "invalid": {
              "INBOX": [
                 "uid1",
41
                 "uid2"
42
43

```

4 Worker Health

As part of the Micronaut framework, each Worker node monitors several components and reports a health check, which is reachable under the path /health.

It's possible to configure the endpoint to be reachable without authentication and provide a simple status output, and then all other details when authenticated.

4.1 Without Authentication

```
curl https://worker:8443/health
```

Sample output:

1

1 2 3

1

```
{
"status" : "UP"
}
```

4.2 With Authentication and Full Details

```
curl -u admin:secret https://worker:8443/health
```

```
Sample output:
```

```
{
       "name": "worker",
       "status": "UP",
       "details": {
         "jdbc": {
           "name": "worker",
           "status": "UP",
           "details": {
             "jdbc:mysql://dmf-db:3306/migration?createDatabaseIfNotExist=true": {
                "name": "worker",
                "status": "UP",
                "details": {
                  "database": "MariaDB",
                  "version": "10.5.4-MariaDB-1:10.5.4+maria~focal"
               }
             }
           }
        },
         "compositeDiscoveryClient()": {
           "name": "worker",
20
21
22
23
24
25
26
27
28
           "status": "UP"
         },
         "diskSpace": {
           "name": "worker",
"status": "UP",
           "details": {
             "total": 126557421568,
             "free": 71800446976,
29
30
             "threshold": 10485760
           }
31
32
33
34
35
        },
         "service": {
           "name": "worker",
           "status": "UP"
         }
36
37
      }
    }
```

4.3 Configuration

Individual health indicators can be turned off with configuration settings, which can be specified through modifying the dmf-worker.yml configuration file or through environment variables.

Configuration Property endpoints.health.disk- space.enabled	Indicator Tree diskSpace	Description Monitors the available disk space of a configurable path and threshold:endpoints.health.disk-space.path
		<pre>(defaults to ".")endpoints.health.disk-space.threshold (in bytes, defaults to 10 MB)</pre>
endpoints.health.jdbc.enabl	eđjdbc	Monitors databases.

5 Worker Metrics

Each Worker node exports a number of metrics, currently all being provided by the Micronaut framework. Its metrics API provides JSON data and also offers a Prometheus API.

Note that authentication is required to query metrics and their values by default.

To change that behavior and not require authentication, set the configuration property endpoints.metrics.sensiti to false, either in the configuration file dmf-worker.yml or in as an environment variable.

The whole metrics API can also be disabled altogether by setting endpoints.metrics.enabled to false.

5.1 List of Metrics

A list of metric names can be queried using

```
curl -u admin:secret https://worker:8443/metrics
```

Sample output:

```
1
2
3
4
5
6
7
8
9
10
    {
      "names": [
         "executor",
         "executor.active",
        "executor.completed",
        "executor.pool.core",
         "executor.pool.max",
        "executor.pool.size",
        "executor.queue.remaining",
         "executor.queued",
11
        "hikaricp.connections",
12
13
14
15
        "hikaricp.connections.acquire",
         "hikaricp.connections.active",
        "hikaricp.connections.creation",
        "hikaricp.connections.idle",
16
17
         "hikaricp.connections.max",
         "hikaricp.connections.min",
18
        "hikaricp.connections.pending",
19
         "hikaricp.connections.timeout",
20
21
22
23
         "hikaricp.connections.usage",
        "jvm.buffer.count",
         "jvm.buffer.memory.used",
         "jvm.buffer.total.capacity",
24
25
26
27
        "jvm.classes.loaded",
        "jvm.classes.unloaded"
         "jvm.gc.live.data.size",
        "jvm.gc.max.data.size",
28
29
        "jvm.gc.memory.allocated",
         "jvm.gc.memory.promoted",
30
        "jvm.gc.pause",
31
        "jvm.memory.committed",
32
         "jvm.memory.max",
33
         "jvm.memory.used",
```

```
34
35
36
         "jvm.threads.daemon",
         "jvm.threads.live",
         "jvm.threads.peak",
37
38
39
         "jvm.threads.states",
         "logback.events",
        "process.cpu.usage",
40
         "process.files.max",
41
         "process.files.open",
42
         "process.start.time",
43
44
45
         "process.uptime",
         "system.cpu.count",
         "system.cpu.usage",
46
         "system.load.average.1m"
47
      ]
48
    }
```

5.2 Query a Metric

Querying a specific metric can be achieved as follows:

```
curl -u admin:secret https://worker:8443/metrics/process.uptime
```

Sample output:

```
1 {
2 "name": "process.uptime",
3 "measurements": [
4 {
5 "statistic": "VALUE",
6 "value": 43.324
7 }
8 ],
9 "description": "The uptime of the Java virtual machine"
10 }
```

5.3 Prometheus Metrics API

The values of all metrics can be fetched in Prometheus' format using the /prometheus endoint:

curl -u admin:secret https://worker:8443/prometheus

A portion of the sample output:

```
# HELP hikaricp_connections_active Active connections
 1
2
   # TYPE hikaricp_connections_active gauge
3
4
   hikaricp_connections_active{pool="HikariPool-1",} 0.0
   # HELP jvm_buffer_memory_used_bytes An estimate of the memory that the Java virtual
        machine is using for this buffer pool
   # TYPE jvm_buffer_memory_used_bytes gauge
5
6
    jvm_buffer_memory_used_bytes{id="direct",} 3.35544376E8
7
8
    jvm_buffer_memory_used_bytes{id="mapped",} 0.0
    # HELP jvm_buffer_total_capacity_bytes An estimate of the total capacity of the buffers in
         this pool
9
   # TYPE jvm_buffer_total_capacity_bytes gauge
10
   jvm_buffer_total_capacity_bytes{id="direct",} 3.35544375E8
   jvm_buffer_total_capacity_bytes{id="mapped",} 0.0
11
```

6 Beyond Dovecot

This documentation discusses the uses of DMF outside of Dovecot. It is not necessary to review this information for a standard DMF deployment.

\land Warning

If you have not read all other documentation, you should go back before proceeding.

As previously noted, while DMF stands for *Dovecot* Migration Framework, in reality, it is more like a *Mail* Migration Framework because nothing actually limits you to Dovecot. In fact, bare bones, it is just a job processing framework that allows you to plug in any Job Worker to process your job.

6.1 Job Workers

The DMF Worker deploys with three Job Workers out of the box.

The type of job worker is configured using the dmf.worker.type property.

6.1.1 Doveadm

The doveadm worker is the standard DMF job worker and it is explained in detail in the DMF Doveadm Features section.

```
1 dmf:
2 worker:
3 type: doveadm
```

6.1.2 Simulator

The simulator worker is used for testing both during development and deployment.

This worker does nothing but sleep for a random amount of time between 1 and 10 seconds inclusive - "simulating" the work.

```
1 dmf:
2 worker:
3 type: simulator
```

6.1.3 Command

The command worker is used to simply execute the migration command. It does nothing more.

The migration command is not converted in the same way that the doveadm worker does it. It does support property injection, however, commands will not be converted to doveadm format and passwords will **not** be hidden.

\land Warning

do not hard code or inject passwords into the migration command.

This worker allows you to execute any kind of command. You could write a shell command which performs the actual mail sync and configure the migration command to use it.

```
1 dmf:
2 worker:
3 type: command
```

6.2 Custom Migration

It's also possible to implement a custom Job Worker to perform the migration in a custom way that the existing workers cannot do and then plug it into DMF.

7 Shipped Packages and Version

7.1 Package open-xchange-dmf-worker

DMF Worker Dovecot Migration Framework Worker. Version: 1.1.0-1 Type: Other

7.1.1 Installation

7.1.2 Configuration

```
For details, please see appendix A /opt/open-xchange/dmf/worker/etc/dmf-worker.yml (page 31)
```

A Configuration Files

```
File 1 /opt/open-xchange/dmf/worker/etc/dmf-worker.yml
```

```

                 operations.
385
             # failure: executed after a migration command failure. When retries are enabled,
                 this is
386
             # only executed if the last retry is a failure, otherwise post is executed.
387
             #
388
             # Commands can have properties injected into them:
389
             # MDB formatters are used like %{mdb:X}, where X can be: md5path, 2chrruid,
                 container,
390
                 uid, ruid, sourcehost, source, sourcepasswd, imapcoptions, email, sourceport,
             #
                  imapc_ssl, exclude
391
             # Conf formatters are used like %(conf:Y}, where Y can be any value defined in
                 the "inject" config
392
                  or: imapc_host, imapc_master_password, imapc_master_user, imapc_prefix,
             #
                 imapc_port
             ####
393
394
             command:
395
               ####
396
               # Custom properties that can be defined and injected into the migration or
397
               # other definable commands. For example, if you define:
398
               # inject:
399
               #
                    test: value
400
               # then you can have a command "doveadm backup -o setting=%{conf:test}" and the
                   command
401
               # would resolve to "doveadm backup -o setting=value"
402
               # The order of injection is:
403
               # 1. inject properties
404
               #
                  2. user properties - from job
405
               #
                  3. imapc properties - from config
406
               ####
407
               inject:
